## Abstract

Hydride-based materials have recently attracted attention because of their significant promotion effect on transition metal catalysts in ammonia synthesis under mild conditions. Here, we clarify the effect of hydride-nitride,  $\text{Ca}_2\text{NH}$ , on the activity and stability of Ru catalyst as a catalyst support for ammonia synthesis. The anionic electrons formed at  $\text{H}^-$  ion vacancy sites in  $\text{Ca}_2\text{NH}$  effectively promote the  $\text{N}_2$  dissociation over Ru surface, which accounts for the high catalytic performance with a low apparent activation energy. The catalytic activity of  $\text{Ru}/\text{Ca}_2\text{NH}$  is much superior to those of  $\text{Ru}/\text{C12A7:e}^-$ ,  $\text{Ru}/\text{Sr}_2\text{NH}$ , and  $\text{Ru}/\text{CaNH}$ . The simple metal hydride,  $\text{CaH}_2$ , with Ru exhibits higher catalytic performance than  $\text{Ru}/\text{Ca}_2\text{NH}$ , but its stability is poor because weak  $\text{Ru}-\text{CaH}_2$  interaction causes aggregation of Ru nanoparticles during the reaction. On the other hand, Ru nanoparticles are anchored on  $\text{Ca}_2\text{NH}$  surface through a strong  $\text{Ru}-\text{N}$  interaction, which leads to excellent stability of  $\text{Ru}/\text{Ca}_2\text{NH}$  catalyst.

Fe-based catalyst at high temperature (400–500 °C) and pressure (10–30 MPa) to obtain high  $\text{NH}_3$  yield (ca. 20%) [1] because efficient  $\text{N}_2$  dissociation requires high temperature from the kinetic point of view whereas  $\text{NH}_3$  yield is limited at high temperatures by thermodynamic equilibrium. Although more than 100 years have passed since the establishment of Haber–Bosch process, ammonia synthesis under low temperature and pressure conditions still presents a major challenge [2]. To date, Ru-based catalysts have been well studied as the second-generation catalyst for  $\text{NH}_3$  synthesis.[3–8] In many cases, Ru nanoparticles are dispersed on carbon or metal-oxide surface and alkali or alkaline earth compounds are added as electronic promoters [9]. These alkali-promoted Ru-based catalysts show high activity at lower temperatures and pressures than Fe-based catalyst. While the alkali-promoters significantly enhance the activity of Ru catalysts, the energy barrier for  $\text{N}_2$  cleavage cannot be reduced, resulting in a high apparent activation energy (80–120  $\text{kJ mol}^{-1}$ ). Additionally, the reaction rate of  $\text{NH}_3$  synthesis over these Ru catalysts is retarded by strong hydrogen adsorption on Ru surface especially at low reaction temperatures [5, 10]. These are common drawbacks of Ru-based catalysts in  $\text{NH}_3$  synthesis.

Recently,  $12\text{CaO } 7\text{Al}_2\text{O}_3$  electride ( $\text{C12A7:e}^-$ ) with 0-dimensional electron confinement and  $\text{Ca}_2\text{N}$  with 2D-confinement were demonstrated to promote the activity of Ru effectively at low reaction temperatures [11–14]. These catalysts enable a significant reduction in activation energy for  $\text{N}_2$  dissociation (50–60  $\text{kJ mol}^{-1}$ ). Anionic electrons with low work function nature (2.3–2.4 eV) in these supports are transferred to the supported Ru nanoparticles, which in turn facilitates  $\text{N}_2$  dissociation on Ru, shifting the bottleneck of ammonia synthesis from the  $\text{N}_2$  dissociation to the formation of  $\text{N-H}_n$  species [12]. Furthermore, both  $\text{Ru/C12A7:e}^-$  and  $\text{Ru/Ca}_2\text{N}$  catalysts have reversible hydrogen absorption–desorption characteristics and this property prevents the hydrogen poisoning on Ru surface.

In the present study, we focused on the promotion effect of  $\text{Ca}_2\text{N}$  on the  $\text{NH}_3$  synthesis activity of Ru catalyst in comparison with various nitride materials. The role of lattice hydrogen and nitrogen in  $\text{Ca}_2\text{N}$  was elucidated by isotope-labelling experiments.  $\text{Ru/Ca}_2\text{N}$  exhibits higher catalytic performance than  $\text{Ru/Sr}_2\text{N}$  with the same crystal structure and similar hydrogen-storage capability. Moreover,  $\text{CaH}_2$ , the simplest hydride, was found to function as an efficient electronic promoter for Ru catalyst in  $\text{NH}_3$  synthesis. Not only the catalytic performance but also the stability of  $\text{Ru/CaH}_2$  and  $\text{Ru/Ca}_2\text{N}$  were discussed on the basis of metal-support interaction.

## Experimental

### Materials

$\text{Ca}_2\text{N}$  powder was prepared by the conventional solid-state reaction as the following procedure. First,  $\text{Ca}_3\text{N}_2$  powder was mixed with Ca metal shots at a molar ratio of 1:1 and the mixture was pressed into a pellet form. The pellet covered with molybdenum foil was heated at 800 °C for 50 h in an evacuated silica tube. Then, the silica tube was rapidly quenched by water. The obtained sample was ground into a powder in an Ar-filled glovebox. As a reference sample,  $\text{Ca}_2\text{NH}$  was synthesized

by heating at 300 °C of  $\text{Ca}_2\text{N}$  powder in a flow of  $\text{N}_2$  and  $\text{H}_2$  ( $\text{N}_2:\text{H}_2=1:3$ , flow rate = 60 ml min<sup>-1</sup>, pressure = 0.1 MPa) and  $\text{CaNH}$  was prepared by the heat treatment of  $\text{Ca}_3\text{N}_2$  at 600 °C in  $\text{N}_2$  and  $\text{H}_2$  gas mixture (flow condition is the same as the above).  $\text{Sr}_2\text{N}$  was synthesized by heating Sr metal at 700 °C for 10 h under  $\text{N}_2$  gas flow.  $\text{CaH}_2$ ,  $\text{SrH}_2$ , and  $\text{BaH}_2$  were prepared by heating each alkaline earth metal at 400 °C (for  $\text{CaH}_2$ ) or 300 °C (for  $\text{SrH}_2$  and  $\text{BaH}_2$ ) for 10 h under high pressure  $\text{H}_2$  atmosphere (2 MPa).

Ru-loading was carried out by heating a mixture of the sample powder and  $\text{Ru}_3(\text{CO})_{12}$  in an evacuated silica tube with the following temperature programme: 2 °C min<sup>-1</sup> up to 40 °C, hold for 1 h; in 2 h up to 70 °C, hold for 1 h; in 2 h up to 120 °C, hold for 1 h; and in 2.5 h up to 250 °C, hold for 2 h; cooling down to ambient temperature. The amount of Ru-loading was fixed to 2 wt%.

## Catalytic reaction

Ammonia synthesis was conducted using 0.1 g of catalyst powder in a fixed bed flow system with a synthesis gas ( $\text{H}_2$ :  $\text{N}_2=3:1$ ) flow rate of 60 ml min<sup>-1</sup> at 0.1 MPa. The produced ammonia was trapped by in a 5-mM sulfuric acid solution, and the amount of  $\text{NH}_4^+$  generated in the solution was determined by ion chromatography (Prominence, Shimadzu) with a conductivity detector.

Ammonia synthesis from  $\text{N}_2$  and  $\text{D}_2$  (or  $^{15}\text{N}_2$  and  $\text{H}_2$ ) was conducted using a U-shaped glass reactor connected to a closed gas circulation system. The mixture gases (total pressure: 60 kPa,  $\text{N}_2$  (or  $^{15}\text{N}_2$ ):  $\text{D}_2$  (or  $\text{H}_2$ ) = 1:3) was introduced into the glass system. The change in the composition of the circulating gas was monitored with a quadrupole mass spectrometer (M-101QA-TDM, Canon Anelva Corp.) and Ar was used as a carrier gas. The circulating pump placed in the system removes diffusional and adsorption/desorption limitations. The  $m/z=2, 3, 4, 16, 17, 18, 19, 20, 28$ , and 30 masses were monitored as a function of time to follow the reaction.  $\text{ND}_3$  ( $m/z=20$ ) was hardly detectable because it overlaps with a fragment of Ar ( $m/z=20$ ).  $\text{N}_2$  isotopic exchange reaction was also conducted using a U-shaped glass reactor in the same way as aforementioned procedure. The mixture of  $^{15}\text{N}_2$  and  $^{14}\text{N}_2$  gases (total pressure: 20.0 kPa,  $^{15}\text{N}_2$ :  $^{14}\text{N}_2=1:4$ ) was used for this reaction. The masses 28, 29 and 30  $m/z$  were monitored as a function of time to follow the exchange.

## Characterization

The crystal structure was identified by X-ray diffractometry (XRD) using a D8 Advance diffractometer (Bruker) with monochromated Cu K $\alpha$  radiation ( $\lambda=0.15418$  nm).  $\text{N}_2$  adsorption–desorption isotherms were measured at 77 K using a specific surface area analyzer (BELSORP-mini II, MicrotracBEL) to determine the Brunauer–Emmett–Teller (BET) specific surface area of samples. Raman spectra of the samples were measured with a spectrometer (HR-800, Horiba Jobin Yvon Co. Ltd., Japan) using a laser with a wavelength of 457.4 nm.

Temperature-programmed absorption (TPA) of  $H_2$  was carried out using a catalyst analyzer (BELCAT-A, MicrotracBEL, Japan). The sample ( $\sim 100$  mg) was heated ( $1^\circ C\ min^{-1}$ ) in a stream of 4.8%  $H_2$ /Ar mixture, and the consumption of  $H_2$  was monitored by a thermal conductivity detector (TCD) and mass spectrometer (Bell Mass, MicrotracBEL, Japan). Temperature-programmed desorption (TPD) of  $H_2$  was performed using the same instrument as TPA experiment. Prior to the TPD measurements, the sample was heated under a mixture of  $H_2$  and  $N_2$ ,  $H_2:N_2=3:1$ ,  $60\ ml\ min^{-1}$ ,  $0.1\ MPa$ ,  $340^\circ C$ ,  $10\ h$ , which are the same reaction condition as those used for ammonia synthesis. After cooling to room temperature, the sample was placed into a TPD glass reactor in an Ar-filled glovebox. The sample was then heated ( $1^\circ C\ min^{-1}$ ) in an Ar stream ( $30\ mL\ min^{-1}$ ), and the concentration of  $H_2$  was monitored by a thermal conductivity detector (TCD) and mass spectrometer (Bell Mass, MicrotracBEL, Japan). TEM (JEM-2010F, Jeol) images of the samples were obtained to determine the microstructural characteristics.

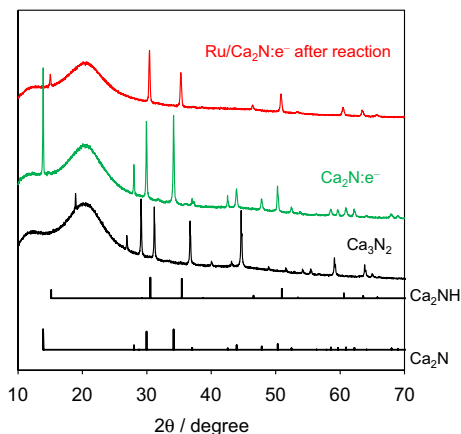

## Results and discussion

### Catalytic performance of Ru loaded $Ca_2N:e^-$

Dicalcium nitride,  $Ca_2N$ , is reported to be a two-dimensional (2D) electride in which electrons are confined between positively charged layers of  $[Ca_2N]^+$  with an inter-layer spacing of  $0.4\ nm$  [15]. Its chemical formula can be expressed as  $[Ca_2N]^+ \cdot e^-$  (denoted as  $Ca_2N:e^-$ ). The open layered-structure provided anisotropic electrical properties (in-plane and out-of-plane work functions =  $2.6$  and  $3.4\ eV$ , respectively) with superior electron concentration ( $N_e = \sim 1.37 \times 10^{22}\ cm^{-3}$ ) than  $C12A7:e^-$  ( $N_e = \sim 2.3 \times 10^{21}\ cm^{-3}$ ) [15, 16]. Accordingly, Ru-loaded  $Ca_2N:e^-$  is expected to function as an efficient catalyst for  $NH_3$  synthesis as with Ru/ $C12A7:e^-$  catalyst.

Figure 1 shows powder X-ray diffraction (XRD) patterns for  $Ca_3N_2$ ,  $Ca_2N:e^-$  and Ru/ $Ca_2N:e^-$  after ammonia synthesis reaction. The broad diffraction patterns observed around  $2\theta = 20$  are not due to sample but to an X-ray transmitting capsule to protect

**Fig. 1** XRD patterns for  $Ca_3N_2$ ,  $Ca_2N:e^-$ , and Ru/ $Ca_2N:e^-$  after ammonia synthesis at  $340^\circ C$  for 20 h. Standard diffraction patterns for  $Ca_2N$  (space group R3m, PDF: 70-4196) and  $Ca_2NH$  (space group Fd3m, PDF: 76-608) are provided for reference

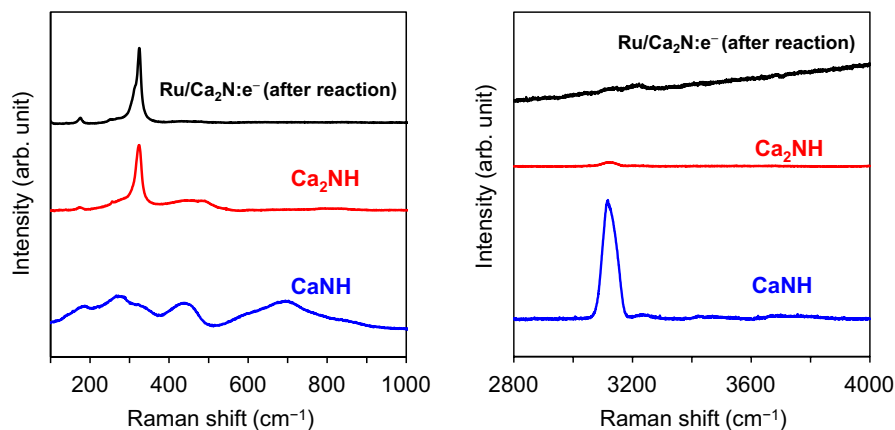

**Fig. 2** Schematic illustration of structural conversion from  $\text{Ca}_3\text{N}_2$  to  $\text{Ca}_2\text{N}:\text{e}^-$  and  $\text{Ca}_2\text{NH}$

sample from oxidation. The  $\text{Ca}_2\text{N}:\text{e}^-$  with a rhombohedral layered structure is synthesized by the solid-state reaction with  $\alpha\text{-Ca}_3\text{N}_2$  powder and Ca metal at  $800^\circ\text{C}$  in vacuum (Fig. 2) according to the following equation:  $\text{Ca}_3\text{N}_2 + \text{Ca} \rightarrow 2\text{Ca}_2\text{N}$ . The  $\text{Ca}_2\text{N}$  phase disappeared in  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  after  $\text{NH}_3$  synthesis, whereas new diffraction peaks arising from the  $\text{Ca}_2\text{NH}$  phase appeared (Fig. 1). The  $\text{Ca}_2\text{NH}$  formation is attributed to the open layered-structure of  $\text{Ca}_2\text{N}:\text{e}^-$ , i.e., hydrogen species spilled over from Ru surface easily enter between the layers and react with anionic electrons to form  $[\text{Ca}_2\text{N}]^+\cdot\text{H}^-$  (Fig. 2). For instance, the  $\text{H}^-$  ion content of  $\text{Ru}/\text{Ca}_2\text{NH}$  reached  $10.6 \text{ mmol g}^{-1}$  after ammonia synthesis reaction at  $340^\circ\text{C}$  for 10 h, which means that all electrons in  $\text{Ca}_2\text{N}$  layers are replaced by  $\text{H}^-$  ions because the theoretical amount of electrons in  $\text{Ca}_2\text{N}:\text{e}^-$  is  $10.5 \text{ mmol g}^{-1}$ . [14] This result is contrary to the case of  $\text{Ru}/\text{C12A7}:\text{e}^-$ , where only 1% of electrons are replaced with  $\text{H}^-$  ions during  $\text{NH}_3$  synthesis at  $360^\circ\text{C}$  because anionic electrons are confined in the cage composed of Ca-O and Al-O bonds [12]. Thus, the formation of  $\text{C12A7}:\text{H}^-$  is restricted to only surface and near-surface region in  $\text{C12A7}:\text{e}^-$ .

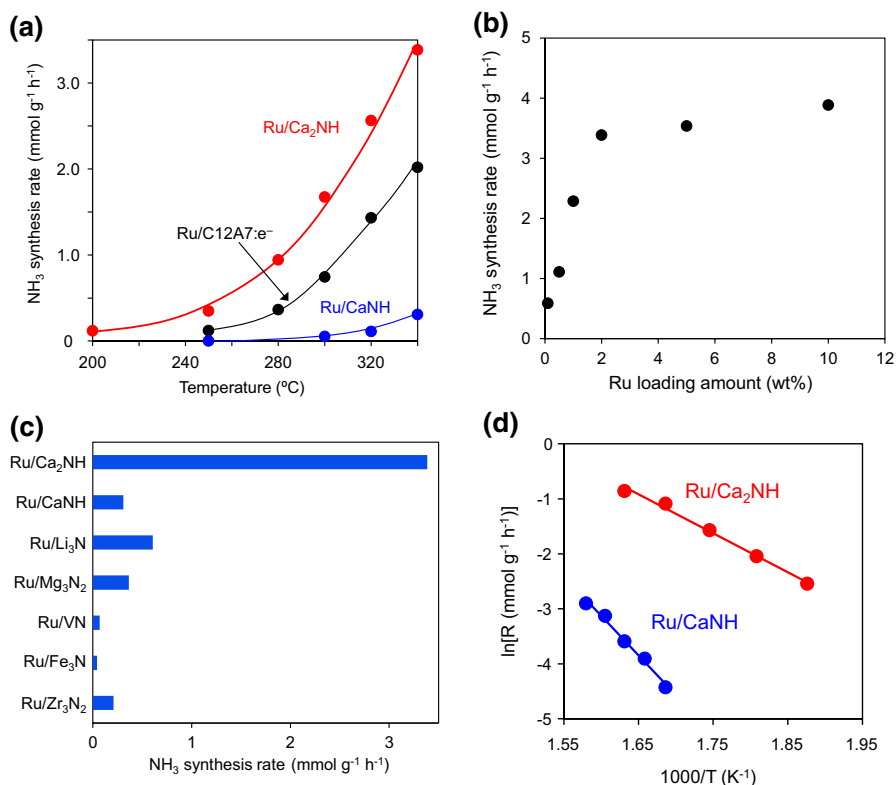

Raman spectroscopy also confirmed that  $\text{Ca}_2\text{NH}$ , an inorganic nitride-hydride, is formed in the  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  catalyst during the  $\text{NH}_3$  synthesis reaction (Fig. 3). Two

**Fig. 3** Raman spectra of  $\text{CaNH}$ ,  $\text{Ca}_2\text{NH}$ , and  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  after ammonia synthesis at  $340^\circ\text{C}$  for 20 h

sharp peaks were observed at 177 and 326  $\text{cm}^{-1}$  for  $\text{Ca}_2\text{NH}$  and used  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  catalyst, whereas several broad bands appeared in the range of 100–1000  $\text{cm}^{-1}$  for  $\text{CaNH}$ . The  $\text{CaNH}$  is composed of  $\text{Ca}^{2+}$  and  $\text{NH}^{2-}$  ions, i.e., the formal charge of hydrogen is +1. Indeed,  $\text{CaNH}$  has an intense band centered at 3122  $\text{cm}^{-1}$ , which is attributed to the N–H stretching mode in imide ions [17–19]. On the other hand, N–H band is negligibly small for the used  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  catalyst which was converted to  $\text{Ca}_2\text{NH}$ , indicating that the hydrogen is formally present as hydride ( $\text{H}^-$ ) ion. Hereafter, the  $\text{Ru}/\text{Ca}_2\text{N}:\text{e}^-$  catalyst is denoted as  $\text{Ru}/\text{Ca}_2\text{NH}$ .

Figure 4a shows the  $\text{NH}_3$  synthesis activity of various Ru (2wt%) catalysts as a function of reaction temperature at atmospheric pressure.  $\text{Ru}/\text{Ca}_2\text{NH}$  exhibited much higher  $\text{NH}_3$  synthesis rate than  $\text{Ru}/\text{C12A7}:\text{e}^-$  and the activity was confirmed even at 200 °C. Accordingly, the apparent activation energy of  $\text{Ru}/\text{Ca}_2\text{NH}$  for  $\text{NH}_3$  synthesis is 60  $\text{kJ mol}^{-1}$ , which is comparable to that of  $\text{Ru}/\text{C12A7}:\text{e}^-$  (50  $\text{kJ mol}^{-1}$ ). In contrast,  $\text{Ru}/\text{CaNH}$  showed low catalytic activity with a high apparent activation energy (110  $\text{kJ mol}^{-1}$ ). Thus,  $\text{Ca}_2\text{NH}$  support serves as strong electron donor to the Ru nanoparticles, reducing the energy barrier for  $\text{NH}_3$  synthesis over  $\text{Ru}/\text{Ca}_2\text{NH}$ . Role of

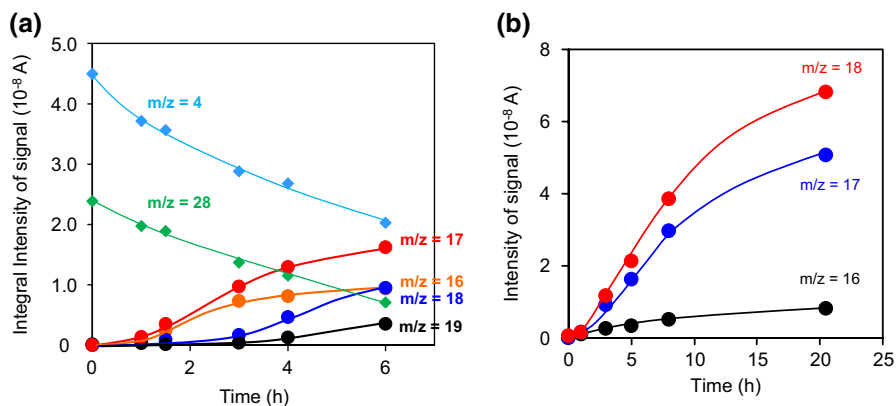

**Fig. 4** **a** Temperature dependence of the rate of  $\text{NH}_3$  synthesis over various Ru catalysts at 0.1 MPa (WHSV, 36,000  $\text{mL g}_{\text{cat}}^{-1} \text{h}^{-1}$ ). **b**  $\text{NH}_3$  synthesis rate for  $\text{Ru}/\text{Ca}_2\text{NH}$  at 340 °C and 0.1 MPa as a function of Ru-loading amount. **c**  $\text{NH}_3$  synthesis rate for various nitride supported Ru catalysts. **d** Arrhenius plots for  $\text{N}_2$  isotopic exchange reaction over various Ru catalysts

loaded Ru promotes the formation of surface H<sup>-</sup> vacancy, in which anionic electron is trapped ( $\text{H}^- \rightarrow 1/2\text{H}_2 + \text{e}^-$ ). Since the formation of  $\text{NH}_2^-$  vacancy is higher than that of H<sup>-</sup> due to higher negative charge, the higher concentration of anion electrons at the anion vacancy is formed on Ca<sub>2</sub>NH than CaNH, which reflects the difference in the catalytic performance between Ru/Ca<sub>2</sub>NH and Ru/CaNH.

Figure 4b shows the dependence of the Ru-loading amount on the catalytic performance of Ru/Ca<sub>2</sub>NH. The NH<sub>3</sub> synthesis rate increases significantly with the Ru loading and reaches an almost constant value ( $\sim 3.5 \text{ mmol g}^{-1} \text{ h}^{-1}$ ) at 2 wt % Ru. It can be considered that Ru nanoparticles are well dispersed up to 2 wt %, but the surface sites on Ca<sub>2</sub>NH is almost occupied at 2wt% due to its low surface area ( $1.5 \text{ m}^2 \text{ g}^{-1}$ ). Figure 4c compares the activities of various nitrides (surface area:  $1\text{--}3 \text{ m}^2 \text{ g}^{-1}$ ) supported Ru catalysts at 340 °C and 0.1 MPa. Ru/Li<sub>3</sub>N and Ru/Mg<sub>3</sub>N<sub>2</sub> have comparable catalytic activity to Ru/CaNH, and the other nitrides supported Ru catalysts show lower activity. On the other hand, Ru/Ca<sub>2</sub>NH catalyst exhibited 5–80 times higher activity than the other catalysts, which suggests that the activity of Ru catalyst is effectively promoted by lattice H<sup>-</sup> ions rather than lattice N<sup>3-</sup> ions. The promotion effect of Ca<sub>2</sub>NH support was further explored by N<sub>2</sub> isotopic exchange reaction ( $^{15}\text{N}_2 + ^{14}\text{N}_2 \leftrightarrow 2^{15}\text{N}^{14}\text{N}$ ) [20–22]. The N<sub>2</sub> dissociation ability of the catalyst can be evaluated by the  $^{15}\text{N}^{14}\text{N}$  production rate. At 360 °C, the reaction rate of Ru/Ca<sub>2</sub>NH is about 30 times higher than that of Ru/CaNH. Moreover, the activation energy of the former ( $59 \text{ kJ mol}^{-1}$ ) is almost half that of the latter ( $120 \text{ kJ mol}^{-1}$ ). It was thus demonstrated that N<sub>2</sub> dissociation is significantly facilitated by electron donation from Ca<sub>2</sub>NH support to Ru.

Ammonia synthesis using isotopically labeled nitrogen ( $^{15}\text{N}_2$ ) and hydrogen (D<sub>2</sub>) was examined to clarify the reaction mechanism over Ru/CaNH. As shown in Fig. 5a, the signals with  $m/z = 19$ , 18, 17, and 16 increases with decreasing N<sub>2</sub> and D<sub>2</sub>. Notably, the signals with  $m/z = 17$  and 16 are much larger than the other signals during the initial reaction period (up to 3 h), meaning that NH<sub>3</sub> was preferentially generated over ND<sub>3</sub>. From this observation, the following reaction mechanism can

**Fig. 5** **a** Reaction time profiles for ammonia synthesis from N<sub>2</sub> and D<sub>2</sub> over Ru/Ca<sub>2</sub>NH at 340 °C. **b** Reaction time profiles for ammonia synthesis from  $^{15}\text{N}_2$  and H<sub>2</sub> over Ru/Ca<sub>2</sub>NH at 340 °C

be proposed. First,  $\text{N}_2$  and  $\text{D}_2$  are dissociated on Ru surface, and the N species on Ru reacts with H species in  $\text{Ca}_2\text{NH}$  to form  $\text{NH}_3$ , whereas D adatoms on Ru tend to be incorporated into the hydrogen vacancy of  $\text{Ca}_2\text{NH}$ . When Ru/ $\text{Ca}_2\text{NH}$  was heated in a mixture of  $^{15}\text{N}_2$  and  $\text{H}_2$ , the signals with  $m/z=18$ , 17, and 16 increased with the theoretical signal ratios ( $^{15}\text{NH}_2(m/z=17)/^{15}\text{NH}_3(m/z=18)=0.8$  and  $^{15}\text{NH}(m/z=16)/^{15}\text{NH}_3(m/z=18)=0.075$ ). Therefore, lattice nitrogen of  $\text{Ca}_2\text{NH}$  is not used in the ammonia synthesis reaction, which is contrary to the rare-earth metal nitride-based catalysts reported recently [23, 24]. These results suggest that ammonia synthesis over Ru/ $\text{Ca}_2\text{NH}$  proceeds through a lattice  $\text{H}^-$  ion-mediated Mars-van Krevelen (MvK) type mechanism [25–27] rather than the direct reaction of N and H adatoms on Ru surface (Langmuir–Hinshelwood mechanism). This MvK-type reaction mechanism was also confirmed by recent DFT calculations [28].

### Comparison of catalytic performance of Ru/ $\text{Ca}_2\text{N}:\text{e}^-$ with Ru/ $\text{Sr}_2\text{N}:\text{e}^-$

$\text{Sr}_2\text{N}$ , a 2D electride with lower work function ( $\sim 2.3$  eV) than  $\text{Ca}_2\text{N}$  [29], was further evaluated as a support of Ru catalyst in ammonia synthesis. As shown in Fig. 6a, the initial ammonia synthesis rate is negligibly small, but the reaction rate increases steeply with reaction time and reaches a constant value of  $1.35 \text{ mmol g}^{-1} \text{ h}^{-1}$  after 22 h. The total  $\text{NH}_3$  produced from this reaction was roughly estimated to be 9 mmol, which is much higher than the mole of lattice nitrogen in  $\text{Sr}_2\text{N}$  (0.53 mmol) per 0.1 g of catalyst. Thus, the Ru/ $\text{Sr}_2\text{N}$  was found to be stable catalyst for  $\text{NH}_3$  synthesis. The presence of  $\text{Sr}_2\text{NH}$  phase may prevent the aggregation of Ru particles through the Ru–N interaction as with the case of Ru/ $\text{Ca}_2\text{NH}$  [30], which accounts for the stable catalytic performance. The  $\text{Sr}_2\text{N}$  phase in Ru/ $\text{Sr}_2\text{N}$  catalyst is expected to be converted into  $\text{Sr}_2\text{NH}$  during the reaction as with the case of Ru/ $\text{Ca}_2\text{NH}$ . The apparent activation energy of Ru/ $\text{Sr}_2\text{NH}$  ( $58 \text{ kJ mol}^{-1}$ ) is almost identical to that of Ru/ $\text{Ca}_2\text{NH}$  ( $59 \text{ kJ mol}^{-1}$ ), implying

**Fig. 6** **a** Reaction time profiles for ammonia synthesis over Ru/ $\text{Sr}_2\text{N}$  at  $340^\circ\text{C}$ . **b** Temperature dependence of the rate of  $\text{NH}_3$  synthesis over Ru/ $\text{Ca}_2\text{NH}$  and Ru/ $\text{Sr}_2\text{NH}$  catalysts at 0.1 MPa (WHSV,  $36,000 \text{ mL g}_{\text{cat}}^{-1} \text{ h}^{-1}$ )

**Fig. 7** **a**  $\text{H}_2$ -TPA profiles for  $\text{Ru/Ca}_2\text{N}$  and  $\text{Ru/Sr}_2\text{N}$  catalysts. **b**  $\text{H}_2$ -TPD profiles for  $\text{Ru/Ca}_2\text{NH}$  and  $\text{Ru/Sr}_2\text{NH}$  catalysts after  $\text{NH}_3$  synthesis reaction at 340 °C for 10 h

that the reaction mechanism is very similar between these catalysts. However, the  $\text{NH}_3$  synthesis rates of  $\text{Ru/Sr}_2\text{NH}$  is less than half that of  $\text{Ru/Ca}_2\text{NH}$  (Fig. 6b).

Temperature-programmed absorption (TPA) and desorption (TPD) of  $\text{H}_2$  on these two catalysts were examined to clarify the difference in their catalytic performance. As shown in Fig. 7, both hydrogen absorption and desorption started at lower temperatures for  $\text{Ru/Ca}_2\text{N}$  as compared with  $\text{Ru/Sr}_2\text{N}$ . These observations come from hydrogen storage and release reaction at the interlayer space ( $\text{H}^0 + \text{e}^- \leftrightarrow \text{H}^-$ ) and this reaction occurs reversibly during ammonia synthesis reaction. Hence, the formation of anionic electron at the  $\text{H}^-$  vacancy site promotes the  $\text{N}_2$  dissociation to form  $\text{NH}_3$  over these catalysts.  $\text{H}_2$ -TPA and TPD experiments revealed that hydrogen absorption–desorption capability of  $\text{Ru/Sr}_2\text{NH}$  is much lower than that of  $\text{Ru/Ca}_2\text{NH}$  below 400 °C, resulting that the density of anionic electrons formed on  $\text{Ru/Sr}_2\text{NH}$  catalyst is much inferior to that for  $\text{Ru/Ca}_2\text{NH}$ . Figure 8 shows the change in the

**Fig. 8** XRD patterns for  $\text{Ru/Sr}_2\text{N}$  **a** before and after ammonia synthesis at 340 °C for **b** 5, **c** 10, and **d** 50 h. XRD pattern for  $\text{SrH}_2$  is provided for reference

XRD patterns for Ru/Sr<sub>2</sub>N with respect to reaction time. The Sr<sub>2</sub>N phase was gradually converted into the mixture of Sr<sub>2</sub>NH and SrH<sub>2</sub>, that is, electrons between Sr<sub>2</sub>N layers are partially replaced by H<sup>-</sup> ions to form Sr<sub>2</sub>NH and a part of Sr<sub>2</sub>N framework is decomposed into SrH<sub>2</sub>. It was therefore demonstrated that the framework structure of Sr<sub>2</sub>N is relatively unstable for NH<sub>3</sub> synthesis than that of Ca<sub>2</sub>N. Nevertheless, the Ru/Sr<sub>2</sub>N catalyst has stable catalytic activity.

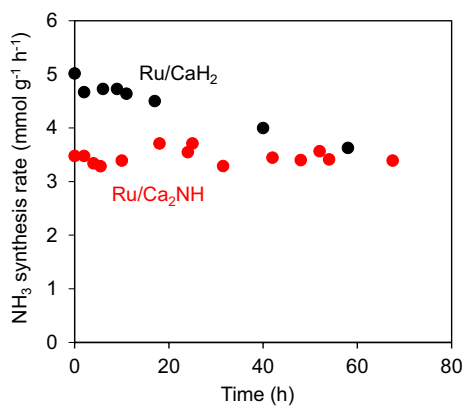

## The role of lattice hydride and nitride on the catalytic performance

To investigate the effect of H<sup>-</sup> ion on the activity of Ru catalyst for NH<sub>3</sub> synthesis, various metal hydrides are examined as a support for Ru catalyst. The catalytic activities of various hydrides supported Ru (2 wt%) catalysts are summarized in Fig. 9. Ru/Ca<sub>2</sub>NH and Ru/Sr<sub>2</sub>NH catalysts exhibited lower catalytic activity than Ru/CaH<sub>2</sub> and Ru/SrH<sub>2</sub>, respectively. The difference in the catalytic activity may be ascribed to the density of H<sup>-</sup> ions at Ru-support interface. More H<sup>-</sup> ions are exposed on the surface for simple metal hydrides such as CaH<sub>2</sub> than for nitride-hydrides such as Ca<sub>2</sub>NH. However, the activity of Ru/CaH<sub>2</sub> continuously decreases with reaction time (Fig. 10). On the other hand, Ru/Ca<sub>2</sub>NH exhibited a stable NH<sub>3</sub> synthesis rate over long periods without degradation in activity. Transmission electron microscopy (TEM) analysis was conducted to investigate the microstructure of Ru nanoparticles on these catalysts during the reaction. As shown in Fig. 11, serious aggregation of Ru particles occurs for Ru/CaH<sub>2</sub> catalyst, where the mean particle size increases from 2.1 nm to 7.5 nm. In addition, it is reported that CaNH phase is slightly generated in Ru/CaH<sub>2</sub> catalyst during NH<sub>3</sub> synthesis [31]. Therefore, the Ru aggregation and CaNH formation leads to the decrease in the number of Ru-hydride interface, resulting in the deactivation of Ru/CaH<sub>2</sub> catalyst. In contrast, Ru nanoparticles with an average size of 2–3 nm are dispersed on Ca<sub>2</sub>NH support and the Ru dispersion is maintained after the prolonged reaction (Fig. 11), which accounts for the high stability of catalytic activity.

**Fig. 12** Schematic illustration of Ru/Ca<sub>2</sub>NH and Ru/CaH<sub>2</sub> catalysts

The difference in the catalytic performance between Ru/Ca<sub>2</sub>NH and Ru/CaH<sub>2</sub> can be explained based on Fig. 12. In the case of Ru/CaH<sub>2</sub>, high density H<sup>−</sup> ions are exposed on the surface of CaH<sub>2</sub>, resulting that a number of anionic electrons with low work function ( $\sim 2.7$  eV) are generated at H<sup>−</sup> ion vacancy sites [32]. As a consequence, N<sub>2</sub> dissociation reaction over Ru is promoted by electron donation from the CaH<sub>2</sub> support, which is attributed to the high catalytic activity at the initial stage of the reaction. However, weak interaction between Ru and H<sup>−</sup> ion causes the aggregation of Ru nanoparticles during the reaction, leading to the degradation of the catalytic activity. As for Ru/Ca<sub>2</sub>NH, the concentration of H<sup>−</sup> ions at Ru-support interface is lower than that for Ru/CaH<sub>2</sub> catalyst, but Ru nanoparticles are immobilized on the Ca<sub>2</sub>NH surface through the strong Ru–N interaction. Hence, the high and stable catalytic performance is realized for Ru/Ca<sub>2</sub>NH catalyst.

## Conclusions

The present study demonstrates that calcium-based nitride hydride, Ca<sub>2</sub>NH, can work as an efficient and stable supports for Ru catalysts in ammonia synthesis. Ru-loaded Ca<sub>2</sub>NH exhibits much higher catalytic activity than various nitride-supported Ru catalysts and Ru/Sr<sub>2</sub>NH with the same crystal structure as Ru/Ca<sub>2</sub>NH. The strong Ru–N bonding on the Ru/Ca<sub>2</sub>NH catalyst works to anchor the Ru nanoparticles to the Ca<sub>2</sub>NH support, resulting in the stable catalytic performance by suppression of agglomeration of the Ru nanoparticles. The present finding reveals that strong electron-donating ability derived from low work function electron formed at H<sup>−</sup> ion vacancy sites as well as strong Ru-support interaction plays a crucial role in high catalytic performance of Ru/Ca<sub>2</sub>NH.

## Memory with Prof. Michel Che

(M.K.) I met Prof. Michel Che for the first time at his lecture held at Osaka Prefecture University when I was a PhD student of Prof. Anpo's laboratory. I was very impressed with his research activity and his approach to understand catalytic process from the molecular level using various spectroscopic techniques. And I remember that he answered my poor English questions politely and kindly. Unfortunately, I

couldn't have the opportunity to discuss with Prof. Michel Che about my research work after I obtained a PhD, but he is my goal as a researcher.

(H.H.) I learned a lot from his review article on active oxygen species oxide surfaces published in 1982. This knowledge led to the discovery of the formation of superoxide radical anion in  $12\text{CaO}\cdot 7\text{Al}_2\text{O}_3$  (C12A7) (Inorg.Chem.1982), which triggered the extensive research on C12A7 including the first RT stable electride materials (Science 2003).
